 ABSTRACT : of one height of the strip. The strip explained the lowering of the soil moisture not only under the tree stand but also at the border of the field. Farther than one height of the strip, its influence on the soil moisture was not observed. An insignificant negative influence of the strip on the evaporation from the field, especially during the spring months, took place within the range of the root system spread of the trees. The influence of the strip on the decrease in the evaporation potential, especially at the distance of 4 strip heights, is stated. At the same time; there was observed no similar effect on the

Title : Photomentering of electric flash lamps

Periodical : Elektrichestvo, 1, 66-68, Ja 1955

Abstract : The author describes a portable laboratory instrument used to measure the radiant energy density of flash lamps. The battery-operated phototube amplifier meter circuit integrates incident light produced at the subject to be photographed by electric flash lamps. The light meter is calibrated for flashes from 10 microsec to 0.1 sec. The author describes the structure, functioning, and calibration procedure. Four diagrams, 4 references (3 Russian, 1946-1952).

TITLE: Device for automatic recording of the distribution of the spectral density of brightness with respect to the channel of a condensed spark discharge

SOURCE: Priory\* 1 tekhnika eksperimenta, no. 4, 1964, 160-166

TOPIC TAGS: automatic recording, brightness spectral density, spark discharge, condensed spark discharge, channel, channel image

Abstract: The article describes a device for automatic recording of the distribution of the spectral density of brightness with respect to the channel of a condensed spark discharge at various times after the beginning of the discharge. The average statistical brightness is recorded for each element of the channel image for a certain number of sparks, which can vary. The device utilizes line-by-line scanning of the channel image of the discharge with respect to the input at the aperture of the spectral device, a delayed gating signal at the output of the photoelectric receiver, and signal storage. There are four figures, one of which is a block diagram of the device for automatic recording.

TITLE: Instantaneous radiation spectra of IFP-200 flash lamp in the visible region

SOURCE: Optika i spektroskopiya, v. 17, no. 2, 1964, 295-297

TOPIC TAGS: photographic flash tube, line spectrum, continuous spectrum, time dependence

ABSTRACT: The spectral characteristics hitherto investigated were confined to lamps with short flash durations ( $<5 \mu\text{sec}$ ). The present investigation concerns a tubular lamp with longer flash duration, the instantaneous spectra being taken at different instants following the start of the flash. The lamp is filled with xenon at 600 mm Hg pressure. The measurement setup is described elsewhere (Yu. M. Kutev and A. V. Aristov, Opt.-mekh. promy\*shl. no. 9, 19, 1960).

Card 1/2

ACCESSION NR: AP4043022

The tests show that in the initial stage of the discharge the radiation is concentrated in a group of spark lines in the wavelength range from 440 to 490 nm. During the later stages of the discharge the intensity of these lines drops and the intensity of the arc lines increases. Unlike spherical flash lamps, tubular lamps have an instantaneous line spectrum and cannot be regarded as black bodies even approximately. Orig. art. has: 1 figure.

surface 8 made up from pyramidal prisms has light filter 9 with a transmittance  $T_3$ . General formulas are deduced for the maximum range of the above system in terms of system and ambient-medium parameters. It is proven that, at ranges of 50 km and longer, the maximum range is mainly limited by the light scattering at the prism surface which, in turn, is determined by the deviation of the prism dihedral angles from  $90^\circ$ . Orig. art. has: 2 figures and 11 formulas.

Abstract : "Snoring" trees the branches of which were uncut attracted a  
large number of pest species and since their moisture evaporated  
more slowly than the moisture of trees with cut off  
branches, numerous beetles preferring "juicy" trees inhabited  
them. Because the maturing of trunk pests in Northern  
Caucasus was a dragged out affair it was necessary to set up  
the "snoring" trees at various periods. Trees felled in winter  
could be "snoring" trees. The habitation of "snoring"  
trees under various conditions was analyzed.

TITLE: Automatic equipment for working out the parallactic angle

SOURCE: IVUZ. Elektromekhanika, no. 8, 1966, 830-840

TOPIC TAGS: parallax computer, telescope equipment, astronomic telescope

ABSTRACT: Analytical expressions are derived associating different angular quantities used to control the position of an azimuthal telescope and generalized computer schemes are considered for computing the parallactic angle  $q$  from these expressions. According to these expressions the parallactic angle  $q$  is a function of the sines and cosines of equatorial and azimuthal coordinates. Computers which carry out sine-cosine transformations may be designed by using rotating transformers. The utilization of such transformers is considered in a universal computer scheme for computing the angle  $q$ , in computer scheme when the angle  $q$  is for latitudes less than  $45^\circ$  and when a difference computer is used to compute  $q$ . A version of the difference computing device for angle  $q$  has been developed and investigated at the Institute of Electromechanics. system uses an asynchronous two phase motor and a solid state amplifier consisting of the following parts: 1) voltage amplifier, 2) automatic volume control circuit,

TITLE: Systems for programmed control of telescopes

SOURCE: AN SSSR. Astronomicheskii soviet. Opticheskaya nestabil'nost' zemnoy atmosfery (Optical instability of the earth's atmosphere). Moscow, Izd-vo Nauka, 1965, 143-149

TOPIC TAGS: stellar astronomy, astronomic telescope, automatic computer programming, atmospheric refraction

ABSTRACT: Systems of programmed automatic control of a telescope were developed and tested at the Institute of Electromechanics as a technical assignment of the Crimean Astrophysical Observatory. Observations were made on only a few stars in order to secure uninterrupted operation and accurate checking. The simplest technique for programming an equatorially mounted telescope was employed. The arrangement for introducing the equatorial coordinates into the computing circuit includes: 1) memory units for storing the constant equatorial coordinates of the small number of stars whose observation is to be programmed, 2) commutators for these coordinates, switching in the circuit for one or the other coordinate, and 3) a program unit to control the commutators and to select the proper star according to the program. Errors due to

Card 1/2

L 14484-66

ACC NR: AT6003719

refraction may be minimized by introducing corrections for average refraction. Further reduction in error is obtained by using rotary transformers for computing correct coordinates and by introducing a unit for considering temperature in refraction calculations. With these modifications, the authors consider it possible to program telescopes for very accurate stellar observations. Orig. art. has: 5 figures, 1 table, and 2 formulas.

TITLE: Colorimetric Determination of Thorium in Ores With Compensation for the Formation of Complexes (Kolorimetriceskoye opredeleniye toriya v rudakh s kompensatsiyey kompleksobrazovaniya)

PERIODICAL: Byul. nauchno-tekhn. inform. M-vo geol. i okhrany nedr SSSR, 1957, Nr 4 (9), pp 76-78

ABSTRACT: The authors propose to determine Th photometrically with arsenazo (I) at a 575-m $\mu$  wave length. The color is stable for several days at pH 1.8-2.3. To remove U<sup>4+</sup>, Zr, Hf, and Ti which impede determination of Th together with the rare earths is precipitated with oxalic acid. The reverse colorimetric titration method is used for the photometric determination of Th. Equal aliquot parts are drawn from a 0.04N solution in HCl and placed in two 25-cc flasks. 0.5-1.0 cc of standard Th solution is added to one, then 5 cc of 0.005% aqueous solution of I are added to each, the mixture is acidulated with HCl to pH 1.6-1.8, the flasks are filled to the mark with water, and the solution is read on the FEK-M photocolormeter. The method is simplified by

Card 1/2

SOV-137 - 58-11-23777

## Colorimetric Determination of Thorium in Ores with Compensation (cont.)

employing test tubes with equal amounts of I solution at pH 1.6-1.8. A quantity of a cc of the solution analyzed is placed in one test tube and a known amount of standard Th solution into the other test tube until the colors are rendered identical after which the same amount of Th solution is added to the second tube and enough of the same solution is added to the first test tube with the solution analyzed until the colors are identical. The X cc of this solution used is the amount looked for and determines the amount of Th in the test tube. The Th content in the test sample is determined according to the formula  $\text{Th}\% = (\text{XP}/\text{T}) \cdot 100$ , where P is the aliquot part of the solution and T is the test sample. The method provides for a determination of  $0.X - 0.00X\%$  Th in an 0.1-1.0 g test sample.

TITLE:

Colorimetric Determination of Thorium by Using Some Azo-  
compounds (Kolorimetricheskoye opredeleniye toriya s  
primeneniye nekotorykh azosoyedineniy)

PERIODICAL:

Vestnik Moskovskogo universiteta. Seriya matematiki,  
mekhaniki, astronomii, fiziki, khimii, 1958, Nr 6,  
pp 99-104 (USSR)

ABSTRACT:

The present investigation was carried out already in 1950;  
additional investigations of "arsenazo" as a reagent to  
thorium were carried out in 1955-56. The following organic  
azo-compounds were used for these investigations: benzene-4-  
sulphonic acid-(-1-azo-5)-8-oxyquinoline (sulphophenazoxine)  
(I), benzene-2-arsonic acid-(-1-azo-1)-2-oxy-naphthalene-3,6-  
disulfonic acid (thoron) (II), benzene-2-arsonic acid-(-1-am-3)-  
4,5-dioxynaphthalene-2,7-disulphonic acid (arsenazo) (III).  
For the investigations solutions of the reagents in ethyl  
alcohol (I) and in water (II) and (III) and a solution of  
thorium nitrate with 0.44 mg Th/ml were used. The optical  
density of the colored thorium solutions (I) and (II) was

Card 1/3

Colorimetric Determination of Thorium by Using Some Azo-compounds 30V/55-58-6-13/8

determined by means of the photometer FM and the thorium content of solution (III) by means of the spectrophotometer SF-4. (I) precipitates Th as a brown precipitate which dissolves in lyes with an orange-yellow color. The intensity of this coloring is proportional to the quantity of thorium in the solution. The determination method developed herefrom is briefly described. The reagent (II), which was first used by Kuznetsov (Ref 3) for a qualitative determination of thorium, gives a coloring together with thorium in a solution containing hydrochloric acid or nitric acid (pH=1), which may be used for the colorimetric determination of Th. It was shown that with an increasing concentration of the reagent in the volume of the solution and with a decrease of the solution volume, quantities of a thousandth part of mg Th in the solution can be colorimetrically determined (Table 1). The determination of thorium is possible also in the presence of large quantities of uranium, cerium and lanthanum (Tables 2-4). The method with thoron has already been worked out by several authors (Refs 3, 4, 5). Arsenazo (III) gives a coloring with many elements (Table 5). Metal compounds with (III) are

Card 2/3

Colorimetric Determination of Thorium by Using Some  
Azo-compounds

30V/55-58-6-13/31

formed at various pH-values. The most interesting compound is formed by Th, which forms in an acid medium, so that it is possible to determine it besides the rare earths and uranium (VI). The method with arsenazo offers the advantage over other methods that the absorption maximum between solution and complex is shifted by 75 m $\mu$  as against only 40 m $\mu$ . Besides, the sensitivity of the reaction (III) with Th is greater than that of (II) with Th. There are 4 figures, 6 tables. and 7 references, 5 of which are Soviet.

TITLE: The Use of the Reagent "Arsenazo" for the Detection of Rare Earths (Primeneniye reaktivnogo arsenaza dlya opredeleniya redkikh elementov)

PERIODICAL: Zavodskaya Laboratoriya, 1958, Vol. 24, No. 3, pp. 10-10-1058 (USSR)

ABSTRACT: "Arsenazo" was suggested by V. I. Kuznetsov (Ref. 1) and has been used generally. The coloration of the compounds of metallic ions with this reagent makes it possible to determine a quantity of one tenth of a microgram of this element in one milliliter of the solution. The optical and chemical properties of solutions of such compounds with various elements (presented in a table) are systematically analysed. It was stated that in the molecule of the reagent two hydrogen ions are substituted by quadrivalent cations and iron (III) ions, whereas trivalent ions and beryllium substitute only one hydrogen ion. According to that, the reactions of formation of complex compounds are described by two equations and two equilibrium constants. By means of substitution of two hydrogen ions, complex compounds are formed in the weakly acid medium (pH = 2,0-2,5) by combination of "arsenazo" with

Card 1/2

SOV/32-24-2-2/51

The Use of the Reagent "Arsenazo" for the Detection of Rare-Earths

titanium, zirconium (hafnium), thorium, uranium, and probably some other quadrivalent actinides, whereas colored solutions are formed by aluminum, gallium, indium, the rare earths yttrium and scandium, and uranyl- and ceryllium ions, due to the lower stability of the complex compounds, only in the weakly acid medium, thereby substituting one hydrogen ion. The latter are anion complexes, as confirmed by the fact that they are adsorbed in the anionite EAE-10-P. The above-mentioned difference of stability of the complex compounds can be used for the separation and detection respectively of certain elements as illustrated by some examples. There are 1 table and 4 references, 3 of which are Soviet.

TITLE: Spectroscopic investigation of the stability of  
complex uranium (VI) compound with fluorine

PERIODICAL: Radiokhimiya, v.3, no.6, 1961, 706-711

TEXT: A brief review of previously reported data for the stability of uranyl fluoride compounds indicated that all such studies were carried out by the potentiometric methods and that no comparative results are available from other investigations. For this reason a spectroscopic examination was made of the stability of uranyl fluoride as judged in terms of variation of the intensity of colour of the uranyl complex produced by reaction with arsenazo reagent. Optical density measurements were made in a CФ-4 (SF-4) spectrophotometer using a cell layer with a thickness of 1 cm at 20 °C. The arsenazo reagent forms with uranyl ions a complex, blue compound, which is easily soluble in water. Solutions of this complex have a maximum spectral absorption at the wavelength of 600 mμ. Changes in the absorption spectra of

Spectroscopic investigation of ...

the complex formed by uranyl ions with arsenazo reagent on addition of sodium fluoride are of the same basic pattern for various sodium chloride concentrations; the optical density at the wavelength of 600 mμ diminishes because of decomposition of a part of the coloured complex in consequence of the formation of colourless uranyl fluoride. In the presence of fluoride, on the other hand, the optical density rises at 500 mμ because the maximum of the absorption spectra of arsenazo solutions corresponds to this wavelength. The quantity of fluoride necessary for the decomposition of the coloured complex rises with the pH of the medium. Data for the equilibrium constants and instability constants of the complex uranyl fluoride ions for the pH range from 3.0 to 5.0 at the total uranium concentration of  $2 \times 10^{-5}M$  and  $3.4 \times 10^{-5}M$  concentration of the arsenazo reagent indicated the formation of a complex uranyl fluoride ion ( $UO_2F^-$ ) with an instability constant of  $1.7 \times 10^{-5}$ . A K. Babko is mentioned in the article in connection with his method for analysis of complex compounds in solutions. There are 4 figures 1 table and 10 references. 9 Soviet bloc and 1 non-Soviet-bloc.

TITLE: Separation of rare earth elements from the accompanying elements in a silica gel filled column

PERIODICAL: Zhurnal analiticheskoi khimii, v. 17, no. 3, 1962, 305-310

TEXT: The separation of Th and Sc from the rare earth elements utilises the difference in hydrolysis of thorium, scandium and other metallic solutions at given pH-values from those of the rare earth elements. The method was adapted also to the separation of aluminium, iron, zirconium, titanium and uranium from rare earth elements. The investigators studied the optimum pH conditions for the separations and also for elution, and for the analysis of the solutions. The cation content of the synthetic solution used was determined by using complexone III and colorimetrically. The column (diameter = 1.4 cm and length 5.0 cm) was filled with silica gel. Washing solutions of ammonium acetate, buffers, and acetic acid were prepared for the pH range 3.5-6.0. Separation of thorium and scandium: Procedure: A mixture of the sample with the buffer mixture is introduced into the column and washed with the buffer solution (2 ml/min). The eluate is collected (25 ml eluate in each beaker) If a rare earth element is present the solution becomes violet ( $\gamma_{\text{max}} = 550-565\text{m}\mu$ ) but in the presence of thorium the color is blue-violet ( $\gamma_{\text{max}} = 575\text{m}\mu$ ). The determination of the cations both in the eluate and those remaining in the column is carried out by titration with complexone III. Thorium

is titrated at pH = 2.0-4.0 and the rare earth element at pH = 6.0-8.0. The end of the washing is tested using arsenazo I. The adsorbed scandium is eluted from the column using 1 N HCl, the solution is neutralized by ammonia and titrated with arsenazo-I. Scandium may be titrated using complexone III in an acid medium with arsenazo-I. The influence of pH on the separation and on the elution of thorium and scandium by this method are explained. The same experiments repeated with mixtures containing rare earth elements and Zr, U, Th, Al and Fe, gave satisfactory results. Deviations varied between  $\pm 0.01$  0.5% (absol.) There are 7 tables and figure.

TITLE: Determination of impurities in graphite by the spectral analysis method

SOURCE: Konstruktsionnyye uglegrafitovyye materialy (Carbon and graphite construction materials); sbornik trudov, no. 1. Moscow, Izd-vo Metallurgiya, 1964, 302-307

TOPIC TAGS: graphite, spectrum analysis, pure element, concentration

ABSTRACT: In order to increase the sensitivity of spectral analysis of graphite, the test sample must be concentrated. It is impossible to use the chemical methods of concentration which are applicable for the spectral analysis of pure metals since graphite dissolves poorly in acids and bases. Calcination is therefore the simplest method to concentrate graphite. The method of concentration proposed by the authors consists of burning the test sample with subsequent analysis of the residue and adding a carrier. A detailed description of this method is given. The use of the calcination method makes it possible to increase the sensitivity of the analysis up to 100 times, depending on the chosen concentration factor for the test sample. When the concentration factor is 100, the sensitivity for various elements in % is: Fe-- $3 \cdot 10^{-7}$ , Mg-- $1 \cdot 10^{-7}$ , Al-- $1 \cdot 10^{-7}$ , Mn-- $1 \cdot 10^{-7}$ , Ti-- $1 \cdot 10^{-6}$  and Cu-- $1 \cdot 10^{-7}$ . TOPIC TAGS: titanium carbide, tungsten steel, carbon steel, metallurgical research, electrolysis, chemical analysis

ABSTRACT: The authors use the phase analysis method for studying materials which contain tungsten, carbon and various quantities of titanium carbide (5, 50 and 90%). The phase composition of the material was established and the state of the carbide phase was determined (quantity, chemical composition, structure). In order to solve these problems, it was necessary to isolate the titanium carbide from the material. The authors verified the possibility of isolating the TiC by chemical dissolution in media which did not dissociate carbides of titanium but dissolved metallic tungsten. The experiments which were conducted and the data of other authors showed that separation of metallic tungsten and titanium carbide is difficult to accomplish by chemical methods. Therefore a method was developed for

ABSTRACT: An electrochemical method was used to determine the phase composition of tungsten base powder materials. It was found that an electrochemical method utilizing citric acid in the electrolyte is best for quantitatively determining tungsten in the presence of its carbide. The largest potential difference between metallic tungsten and its carbide was observed with citric anions of pH = 3. This difference was as large as 600 mv. Furthermore, the smallest amount of carbide loss (5-7%) was obtained in the citric acid electrolyte. N. A. Tsapkova took part in these experiments. Orig. art. has: 3 figures and 2 tables.

TOPIC TAGS: niobium, hydroxyquinoline, chemical analysis, niobium analysis, refractory, titrimetric determination

ABSTRACT: The developed method for determination of niobium by 8-hydroxyquinoline (HQ) precipitation avoids the tedious washing of the precipitate. Precipitation of niobium is carried out with a standard solution of HQ. After precipitation it simply involves bromatometric titration of the excess HQ in the filtrate. The developed method for determination of niobium in carbides and borides had precision of  $\pm 0.5\%$  with the additional advantage of being rapid.

SOURCE: Zavodskaya laboratoriya, v. 30, no. 10, 1964, 1189-1190

TOPIC TAGS: titanium, chemical analysis, titanium compound, quantitative analysis, titanium carbide, titanium diboride

ABSTRACT: A method was developed to determine quantitatively titanium carbide and titanium diboride in the mixture  $TiC + TiB_2 + TiSi_2 + SiC + B_4C$ . Any solvent used for this purpose should not dissolve titanium disilicide, silicon carbide, and boron carbide. The solvent selected is a solution of  $H_2SO_4$  (1:4) and  $H_2O_2$  which is mixed, boiled for one hour, diluted, and used to leach the titanium carbide and diboride from the original mixture. Filtration removes the insoluble compounds; treatment of the filtrate by the volumetric method with glycerin with careful separation of reaction by-products permits the obtaining of boron and titanium quantities. Experiments were performed to measure boron and titanium quantities by the given method for various phase-mixing conditions. Results were subsequently compared with theoretical values and were found to be very satisfactory. The results are presented in a table. Orig. art. has: 1 table.

SOURCE: Zavodskaya laboratoriya, v. 30, no. 11, 1964, 1328-1329

TOPIC TAGS: zirconium, zirconium compound, zirconium dioxide, hydrofluoric acid, sulfuric acid, nitric acid

ABSTRACT: The different solubility of Zr, ZrC, and ZrO<sub>2</sub> in hydrofluoric, sulfuric, and nitric acids was used in the analysis of a mixture (0.1 g each of Zr, ZrC, and ZrO<sub>2</sub>) of these substances. Although HF (diluted 1:5 with water) dissolves the metallic Zr as well as some ZrC, treatment of the mixture (0.3 g) for 15-20 minutes with more dilute HF (1:20) (40 ml) dissolved only the metal and not the ZrC and ZrO<sub>2</sub>. The residue was boiled 30-40 minutes in 40 ml of H<sub>2</sub>SO<sub>4</sub> (1:2) with 15 drops of concentrated nitric acid, adding water to keep the volume constant. The residue was heated 20-30 minutes (without boiling) in 10 ml concentrated fluoric acid; then 20 ml of H<sub>2</sub>SO<sub>4</sub> were added, and the solution was heated until dense white vapor began forming. The Zr content in the three solutions was determined and related to the

TITLE: Spectrochemical determination of boron traces in semiconductor graphite 15

SOURCE: Zavodskaya laboratoriya, v. 30, no. 11, 1964, 1348-1349

TOPIC TAGS: high purity graphite, semiconductor graphite, graphite spectrochemical analysis, trace analysis, boron trace determination, boron concentration

ABSTRACT: A spectrochemical method of boron determination in graphite has been developed, whereby partial combustion of the graphite and utilization of the sample itself as an electrode in a d-c arc eliminated a source of error attributed to the low volatility of boron carbide. At the same time enrichment of the sample in boron made it possible to increase the sensitivity of spectroscopic determination. Calcium hydroxide in solution was added to the samples prior to their calcining to prevent possible losses of boron as  $B_2O_3$ . Powdered samples partially calcined at 800C were compacted with sugar syrup as a binder. The tablets obtained were used as the anode and the compacted, boron-free graphite as the cathode in an arc excitation system. Analysis was carried out on an

Card 1/2

L 12463-65

ACCESSION NR: AP4048365

ISP-28 spectrograph. Spectra of the samples and synthetic standards were recorded photographically. The standards were prepared from high-purity graphite with boron added in the form of boric acid. The operating procedure is described. The sensitivity of the method is  $10^{-6}$ — $10^{-7}\%$  boron, and the average relative error 10%. Orig. art. has: 1 table.

TITLE: Tectonic Geology of the Olenek, Markha, Muna, and Linde Rivers Region (Tektonika mezhdurech'ya Oleneka, Markhi, Muna i Linde)

PERIODICAL: Doklady Akademii nauk SSSR, 1956, Vol 102, Nr 3, pp 453-456 (USSR)

ABSTRACT: The region of the Olenek, Markha, Muna and Linde Rivers lies from a tectonic standpoint within the realm of the Sibirskaya platforma (Siberian Platform) as well as on the junction of two tectonic elements: the Severno Sibirskaya glyba (Northern Siberian Fragment) and the Vilyuyskaya Syncline (Ref 4). This heretofore poorly studied part of the Siberian Platform has now been studied in detail following the geologic mapping (1 : 1000 000) of the Vilyuyskaya ekspeditsiya Vsesoyuznogo geologicheskogo tresta (Vilyuy Expedition of the All Union Aerial Geological Trust) and of several expeditions of the Institut geologii Arktiki (Institute of Arctic Geology). The studies have afforded a correct if also somewhat schematic determination of the structure of the region (Ref 6). A large group of geologists under the leader-

ship of B. N. Leonov has completed the work. Contributors to the project are R. A. Bidzhiyev, M. M. Bobrinskiy, V. V. Gritsik, Ye. S. Kutoynikov, L. M. Natapov, N. G. Nikanorov, B. I. Prokopchuk, V. M. Rybchenkov, S. V. Tishchenko, N. A. Tseydler, Yu. T. Shvyryayev, V. N. Shirikov and others. For the work a new method was employed: single stratigraphic units were traced and mapped on aerial photographs and on topographic maps (Ref 2). As the map (Fig 2) shows, the region has a rather complicated structure. In the southwestern corner of the area, on the right bank of the Markha River, the beds dip at a low angle (15') to the southwest in the direction of Tungusskaya Syncline. This part of the region lies at the edge of a wide fault zone. This zone penetrates the aforementioned syncline; it is called Vilyuysko-Kotuyanskaya Zone (Ref 1). Large intrusions have penetrated the fault zone, allowing it to be easily traced on the surface. The monoclinical east limb of the syncline gradually becomes flatish in the southwest limb of the Markhinskiy val, an elongate anticlinal structure (Ref 2). Paralleling this structure and crossing the head waters of the Tyung River near the mouth of the Argaa-Tyung River and extending towards the head waters of the Muna and Bekke Rivers is a flat anticlinal

structure, the Tyungo-Siligirskiy val (Tyung-Siligir Anticline). On the aerial photographs a single brachyanticline can be determined in the folded region between the above mentioned anticlines, in the area of the upper waters of the Khanni, Ulakh-Muna and Argan-Tyung Rivers. Between the Tyungo-Siligirskiy Anticline and the Munskeye podnyatiye (Muna Uplift) is a broad synclinal structure, the Olenekskiy (on the Olenek River). Somewhat further south from the Muna Uplift there is an intensive magnetic anomaly, the Shiganskaya (Ref 3). At the southeastern border of the Markha- and Tyung-Siligirskiy Anticlines, as well as at the Olenek flexure, is a structural depression in the northern part of the Vilyuyskaya Syncline. It is called the Vilyuysko-Markhinskaya flexura (Vilyuy-Markha Flexure). In the region of this flexure as well as on the slope of the Muna Uplift, dikes and trap intrusions are developed which have intruded along faults. During the Middle Cambrian, the entire Leno-Olenekskiy River region was covered by a relatively shallow ocean. Middle Cambrian marine sediments outcrop on the Muna Uplift as well as outside of the region here discussed. Towards the end of the Middle Cambrian and in the Upper Cambrian the Olenek

region was intensively folded and a 1000 to 2000 m thick carbonate mass was deposited. The Vilyuy-Markha-Flexure and the associated faulting may have originated towards the end of the Triassic or early Jurassic. There are 1 figure and 6 references, 6 of which are Soviet.
